Objectives of this book

Bloc’s design is getting stable and this book is a first tutorial on Bloc. Some elements may change such as the name of certain methods, but most of these changes will be minor.

In this tutorial you will build a memory game. We provide the model and focus on creating the UI of the game.

1.1 Memory game

Let us have a look at what we want to build with you: a simple Memory game. In a memory game players need to find pairs of similar cards. In each round a player turns over two cards at a time. If the two cards show the same symbol they are removed and the player gets a point. If not, they are both flipped.

For example, Figure 1-1 shows the game after the first selection of two cards. Face-down cards are represented with a cross and turned cards are just showing a number. Figure 1-2 show the same game after a few rounds. While this game can be played by multiple playes, in this tutorial we will build a game with just one player.

To start with, here is the code that builds and launches the game:

```smalltalk
game := MgdGameModel new initializeForSymbols: '12345678'.
grid := MgdGameElement new.
grid memoryGame: game.

space := BlSpace new.
space extent: 420@420.
space root addChild: grid.
space show
```
Objectives of this book

Figure 1-1 The game after the player selected two cards: faced-down cards are represented with a cross and turned card with their number.

- first, we create a game model and ask to get the numbers from 1 to 8 associated with the cards. By default a game model has a size of 4 by 4, which requires eight different cards.
- Second, we create a graphical game element.
- Third, we assign the model of the game to the UI.
- Finally, we create a graphical space in which we place the game UI and we display the space.

1.2 Getting started

This tutorial is for Pharo 60 running on the latest Pharo60 Virtual machine. You can get them at the following address

http://get.pharo.org/60+vm

Alternatively, you can download them by executing the line below on a Linux or MacOs system:

wget -O- get.pharo.org/60+vm | bash

To load Bloc execute the following snippet:

\[
\begin{align*}
\text{Metacello new} \\
\text{baseline: 'Bloc';}
\end{align*}
\]
1.3 Loading the Memory Game

To make the demo easier to follow and help you if you get lost we already made a full implementation of the game. You can load it using the following code:

```metacello
Metacello new
    baseline: 'BlocTutorials';
    repository: 'github://pharo-graphics/Tutorials/src';
    load
```

After you loaded the BlocTutorials project, you will get two new packages: Bloc-MemoryGame and Bloc-MemoryGame-Demo. Bloc-MemoryGame contains the full implementation of the game. Just to the class side of MgExamples and click on the green triangle next to the open method to start the game. Bloc-MemoryGame-Demo is a skeleton for the game that we will use in this tutorial.

![Figure 1-2](image-url) Another state of the memory game after the player correctly matched two pairs.
Before starting with the actual graphical elements, we first need a model for our game. This game model will be used as a model in the typical Model View architecture. On the one hand, the model does not communicate directly with the graphical elements; all communication is done via announcements. On the other hand, the graphic elements are communicating directly with the model.

In the remainder of this chapter we describe the game model in details. If you want to move directly to building graphical elements using Bloc, the package Bloc-MemoryGame-Demo already contains the model.

### 2.1 Reviewing the card model

Let us start with the card model: a card is an object holding a symbol to be displayed, a state representing whether it is flipped or not, and an announcer to emit state changes. This object could also be a subclass of Model which already provide announcer management.

``` Smalltalk
Object subclass: #MgdCardModel
  instanceVariableNames: 'symbol flipped announcer'
  classVariableNames: '
  package: 'Bloc-MemoryGame-Demo-Model'

MgdCardModel >> initialize
  super initialize.
  flipped := false
```
2.2 Card simple operations

Next we need two API methods to flip a card and make it disappear when it is no longer needed in the game.

```smalltalk
MgdCardModel >> flip
    flipped := flipped not.
    self notifyFlipped

MgdCardModel >> disappear
    self notifyDisappear
```

2.3 Adding notification

The notification is implemented as follows in the notifyFlipped and notifyDisappear methods. They simply announce events of type MgdCardFlippedAnnouncement and MgdCardDisappearAnnouncement. The graphical elements will have to register subscriptions for these announcements as we will see later.

```smalltalk
MgdCardModel >> notifyFlipped
    self announcer announce: MgdCardFlippedAnnouncement new

MgdCardModel >> notifyDisappear
    "Notify all observers that I disappeared from the game"
    self announcer announce: MgCardDisappearAnnouncement new
```

Here, MgdCardFlippedAnnouncement and MgdCardDisappearAnnouncement are just subclasses of Announcement.

```smalltalk
Announcement subclass: #MgdCardFlippedAnnouncement
    instanceVariableNames: ''
    classVariableNames: ''
    package: 'Bloc-MemoryGame-Demo-Events'

Announcement subclass: #MgdCardDisappearAnnouncement
    instanceVariableNames: ''
    classVariableNames: ''
    package: 'Bloc-MemoryGame-Demo-Events'
```
2.4 Reviewing the game model

We add one final method to print a card in a nicer way and we are done with the card model!

```smalltalk
MgdCardModel >> printOn: aStream
    aStream
        nextPutAll: 'Card';
        nextPut: Character space;
        nextPut: $(;
        nextPut: self symbol;
        nextPut: $)
```

2.4 Reviewing the game model

The game model is simple: it keeps the tracks of all the available cards and all the cards currently selected by the player.

```smalltalk
Object subclass: #MgdGameModel
    instanceVariableNames: 'availableCards chosenCards'
    classVariableNames: ''
    package: 'Bloc-MemoryGame-Demo-Model'
```

The initialize method set two collections for the different cards.

```smalltalk
MgdGameModel >> initialize
    super initialize.
    availableCards := OrderedCollection new.
    chosenCards := OrderedCollection new

MgdGameModel >> availableCards
    ^ availableCards

MgdGameModel >> chosenCards
    ^ chosenCards
```

2.5 Grid size and card number

We hardcode for now the size of the grid and of the number of cards that need to be matched by a player.

```smalltalk
MgdGameModel >> gridSize
    "Return grid size, total amount of card is gridSize^2"
    ^ 4

MgdGameModel >> matchesCount
    "How many chosen cards should match in order for them to disappear"
    ^ 2

MgdGameModel >> cardsCount
    "Return how many cards there should be depending on grid size"
    ^ self gridSize * self gridSize
```
2.6 Initialization

To initialize the game with cards we add a dedicated method, `initializeForSymbols:`. This method creates a list of cards from a list of characters and shuffle it. We also add an assertion in this method to verify that the called provided enough characters.

```snippet
MgdGameModel >> initializeForSymbols: characters

self assert: [ characters size = (self cardsCount / self matchesCount)]
description: [ 'Amount of characters must be equal to possible all combinations' ].
availableCards := (characters asArray collect: [:aSymbol |
(1 to: self matchesCount) collect: [:i |
    MgdCardModel new symbol: aSymbol ]]) flattened shuffled asOrderedCollection
```

2.7 Game logic

Next we need `chooseCard:`, a method that will be called when a user selects a card. This method is actually the most complex method of the model and implements the main logic of the game. First, the method makes sure that the selected card is not already selected. This could happen if the view uses animations that give players the chance to click on the card more than once. Next, the card is flipped by sending it the message `flip`. Finally, depending on the actual state of the game the step is complete and the selected cards removed, or all selected cards are flipped back.

```snippet
MgdGameModel >> chooseCard: aCard

(self chosenCards includes: aCard)
ifTrue: [ ^ self ].
self chosenCards add: aCard.
aCard flip.
self shouldCompleteStep ifTrue: [
    ^ self completeStep ].
self shouldResetStep ifTrue: [
    self resetStep ]
```

The current step is completed if the player selected the right amount of cards and they all show the same symbol. In this case, all selected cards receive the message `disappear` and are removed from the list of selected cards.

```snippet
MgdGameModel >> shouldCompleteStep

^ self chosenCards size = self matchesCount
    and: [ self chosenCardMatch ]
```
2.8 Ready

```smalltalk
MgdGameModel >> chosenCardMatch
    | firstCard |
    firstCard := self chosenCards first.
    ^ self chosenCards allSatisfy: [ :aCard |
        aCard isFlipped and: [ firstCard symbol = aCard symbol ] ]

MgdGameModel >> completeStep
    self chosenCards
do: [ :aCard | aCard disappear ];
removeAll.
```

The current step should be reset if the player selected a third card. This will happen when a player already selected two cards that did not match and clicked on a third one. In this situation the two initial cards will be flipped back. The list of selected cards will only contain the third card.

```smalltalk
MgdGameModel >> shouldResetStep
    ^ self chosenCards size > self matchesCount

MgdGameModel >> resetStep
    |lastCard|
    lastCard := self chosenCards last.
    self chosenCards
        allButLastDo: [ :aCard | aCard flip ];
        removeAll;
        add: lastCard
```

2.8 Ready

We are now ready to start building the game view.

Since Bloc is still under development, it may happen that you will get exceptions after which graphical elements do not render correctly. In that case the Universe has to be reinitialized.

```smalltalk
BlUniverse reset
```
In this chapter we will build step by step the visual appearance of the cards. In Bloc visual objects are called elements and usually you define a subclass of BlElement, the inheritance tree root. In subsequent chapters we will do the same for the game and add interaction using event listeners.

### 3.1 First: the card element

A graphic element is a subclass of the BlElement. It simply has a reference to a card model.

```smalltalk
BlElement subclass: #MgdCardElement
  instanceVariableNames: 'card'
  classVariableNames: ''
  package: 'Bloc-MemoryGame-Tutorial'

The message backgroundColor is one of the customisation hooks defined in BlElement. Let us define a nice color.

```smalltalk
MgdCardElement >> backgroundColor
  ^ Color lightBlue
```

We mentioned the accessors since the setter will be place to hook registration for the communication between the model and the view.

```smalltalk
MgdCardElement >> card
  ^ card

MgdCardElement >> card: aMgCard
  card := aMgCard
```

We initialize it to get a
Building card graphical elements

Figure 3-1  A first extremely basic representation of face down card.

```small
MgdCardElement >> initialize
   super initialize.
   self size: 80 @ 80.
   self card: MgdCardModel new
```

3.2 Starting to draw a card

To define the visual properties of a graphic element we redefine the method `drawPathOnSpartaCanvas:`.

(This method will be renamed `drawPathOn:` in the future).

```small
MgdCardElement >> drawPathOnSpartaCanvas: aCanvas
   super drawPathOnSpartaCanvas: aCanvas.
   aCanvas fill
      paint: self backgroundColor;
      path: self boundsInLocal;
      draw
```

Note that if we forget to send the message `draw` the canvas will be set but it will not display the result.

Now to see the result in Morphic we have to get a spartaForm as follows:

```small
MgdRawCardElement new asSpartaForm
```

You can also use the the inspector as shown in Figure 3-1. Here we create and inspect the graphic element and then we ask for its form and look at it in the Morph pane (this is what the Preview pane is actually doing).
3.3 Improving the card visual

Instead of displaying a full rectangle, we want a better visual. Bloc offers a shape factory. This shape factory returns shape path (lines, rectangle, ellipse, circle...) that can be passed to the canvas using the message path:. Other shapes can be easily added.

For example with the following expression path: (aCanvas shape ellipse: self boundsInLocal) we draw now a circle since the bounds of the receiver returns a square of 80.

```smalltalk
MgdCardElement >> drawPathOnSpartaCanvas: aCanvas

| radius |
super drawPathOnSpartaCanvas: aCanvas.
radius := 12.
aCanvas fill
    paint: self backgroundColor;
    path: (aCanvas shape ellipse: self boundsInLocal);
draw
```

For our card we would like to have a rounded rectangle so we use the roundedRectangle:radii: factory message.

```smalltalk
MgdCardElement >> drawPathOnSpartaCanvas: aCanvas

| radius |
super drawPathOnSpartaCanvas: aCanvas.
radius := 12.
aCanvas fill
    paint: self backgroundColor;
    path: (aCanvas shape roundedRectangle: (self boundsInLocal)
        radii: (BlCornerRadii radius: 12));
draw
```

You should get then a visual representation close to the one shown in Figure 3-2.

3.4 Preparing flipping

We define now two methods

```smalltalk
MgdCardElement >> drawBacksideOn: aCanvas
    "nothing for now"
MgdCardElement >> drawFlippedOnCanvas: aCanvas
    "nothing for now"
```

And we refactor drawPathOnSpartaCanvas: as follows: we extract the common part into a separate method.
Building card graphical elements

Figure 3-2  A rounded card.

```smalltalk
MgdCardElement >> drawCommonOnCanvas: aCanvas
    | radius |
    super drawPathOnSpartaCanvas: aCanvas.
    radius := 12.
    aCanvas fill
    paint: self backgroundColor;
    path: (aCanvas shape roundedRectangle: self boundsInLocal radii: (BlCornerRadii radius: 12));
    draw.
```

Finally, drawPathOnSpartaCanvas: logic is at the same conceptual level.

```smalltalk
MgdCardElement >> drawPathOnSpartaCanvas: aCanvas
    super drawPathOnSpartaCanvas: aCanvas.
    self drawCommonOnCanvas: aCanvas.
    self card flipped
    ifTrue: [ self drawFlippedOnCanvas: aCanvas ]
    ifFalse: [ self drawBacksideOn: aCanvas ]
```

Now we are ready to implement the backside and flipped side

3.5 Adding a cross

Now we are ready to define the backside of our card. We will start by drawing a line. To draw a line we should provide it as a path. In Bloc this can be done by either passing a Path object or by asking the canvas for its shape factory. The shape factory encapsulates the logic of shapes. This is what we do below with the expression path: (aCanvas shape line: 0 @ 0 to: self extent). The message shape returns a ShapeFactory and we ask this factory to produce a path to produce a line.

```smalltalk
MgdCardElement >> drawBacksideOn: aCanvas
    aCanvas stroke
    paint: Color paleBlue;
    path: (aCanvas shape line: 0 @ 0 to: self extent);
```
3.6 Lines and corners reconciled

Figure 3-3  A rounded card with half of the cross.

\[
\text{draw}
\]

Once this method is defined, refresh the inspector and you should get a card as in Figure 3-3.

3.6 Lines and corners reconciled

In Figure 3-3 we see that the line is not clipped to the corners. We should address this. This is the way we did it for now.

MgdCardElement >> drawBacksideOn: aCanvas
| radiusOffset |
radiusOffset := 12 / Float pi.
aCanvas stroke
  paint: Color gray;
  width: 3;
  path: (aCanvas shape
    line: radiusOffset @ radiusOffset
to: self extent - radiusOffset);
draw

Once you change the method drawBacksideOn: and refresh you should get a card as displayed in Figure 3-4.

3.7 Full cross clipped

Now we can add the line to build a full cross. Our solution is defined as follows:

MgdCardElement >> drawBacksideOn: aCanvas
| radiusOffset |
radiusOffset := 12 / Float pi.
aCanvas stroke
  paint: Color paleBlue;
  width: 3;
Building card graphical elements

Figure 3-4  Clipping line.

Figure 3-5  A card with a complete backside.

```
path: (aCanvas shape
   line: radiusOffset @ radiusOffset
   to: self extent - radiusOffset);
draw.
aCanvas stroke
   paint: Color paleBlue;
   width: 3;
path: (aCanvas shape
   line: (self width - radiusOffset) @ radiusOffset
   to: radiusOffset @ (self height - radiusOffset));
draw
```

Now our backside is fully implemented and when you refresh your view, you should get the card as shown in Figure 3-5.

3.8 Flipped side

Now we are ready to develop the flipped side of the card. To see if we should change the card model. You can use the inspector to get the cardElement and send it the message `card flip` or directly recreate a new card as follows:
3.8 Flipped side

![Image](image.png)

**Figure 3-6** A card with a complete backside.

```plaintext
| cardEl |
cardEl := MgdCardElement2 new.
cardEl card flip.
cardEl asSpartaForm
```

You should get an inspector in the situation shown in Figure 3-6. Now we are ready to implement the flipped side.

Let us redefine `drawFlippedOnCanvas:` as follows:

- First we ask the canvas to build a font of size 50. Note that for the font we specify a FreeType font (pay attention that strike fonts do not work and will never work in Bloc - in fact they will be removed once Pharo is based on Bloc).

- Then we ask the canvas to draw a text using the font with the color we want.

We should not forget to send the message `draw` to the canvas.

```plaintext
MgdCardElement >> drawFlippedOnCanvas: aCanvas
| font |
font := aCanvas font
    named: 'Source Sans Pro';
    size: 50;
    build.
aCanvas text
    font: font;
paint: Color gray;
string: self card symbol asString;
draw
```

When we refresh the display we do not see the symbol and this is a problem. If you pay attention you will see that there is just one line that is drawn on the top left of the card. You can change the color to red to see it on the card. We are drawing the string in the corner and outside the rounded rectangle. Let us fix that issue by defining the baseline from which the text should be displayed.
Building card graphical elements

Figure 3-7  Not centered letter.

When you refresh the inspector you should see the card symbol but not centered as shown in Figure 3-7.

To center the text well, we have to use exact font metrics. Bloc can support multiple graphical back-end such as Cairo, Moz2D and in the future plain openGL. There is one important constraint, that is that font metrics should be measured and manipulated via the same back-end abstraction. For this purpose, the expression `aCanvas text` returns a text painter and such a text painter provides access to the font measurements. Using such measurements we can then get access to the text metrics and compute a better center.
With this definition we get the letter centered vertically but not horizontally. This is because we have to take into account the font size.

```smaller
MgdCardElement >> drawFlippedOnCanvas: aCanvas
| font origin textPainter metrics |
font := aCanvas font
    named: 'Source Sans Pro';
    size: 50;
    build.

textPainter := aCanvas text
    font: font;
    paint: Color paleBlue;
    string: self card symbol asString.

metrics := textPainter measure.

origin := (self extent - metrics textMetrics bounds extent) / 2.

textPainter
    baseline: origin;
    draw
```

With this definition we get a centered letter as shown in Figure 3-8.

Now we are ready to work on the board game.
In the previous chapter, we defined all the card visualization. We are now ready to define the game board visualization. Basically we will define a new element subclass and set its layout.

Here is a typical scenario to create the game: we create a model and its view and we assign the model as the view’s model.

```blocks
game := MgdGameModel numbers.
grid := MgdGameElement2 new.
grid memoryGame: game.
```

4.1 The GameElement class

Let us define the class MgdGameElement that will represent the game board. As for the CardElement, it inherits from the BlElement class. This view object holds a reference to the game model.

```blocks
BlElement subclass: #MgdGameElement
  instanceVariableNames: 'memoryGame'
  classVariableNames: '
  package: 'Bloc-MemoryGame-Tutorial'
```

We define the memoryGame: setter method. We will extend it just after to create all the cards element.

```blocks
MgdGameElement >> memoryGame: aMgdGameModel
  memoryGame := aMgdGameModel

MgdGameElement >> memoryGame
  ^ memoryGame
```
During the object initialization we set the layout (i.e., how sub elements are placed inside their container). Here we define the layout to be a grid layout and we set it as horizontal.

```small
MgGameElement >> initialize
  super initialize.
  self layout: BlGridLayout horizontal.
```

### 4.2 Creating cards

When a model is set for a board game, we use the model information to perform the following actions:

- we set the number of columns of the layout
- we create all the card elements paying attention to set their respective model.

Note in particular that we add all the cards graphical elements as children of the board game using the message `addChild:`.

```small
MgdGameElement >> memoryGame: aGameModel
  memoryGame := aGameModel.

  memoryGame availableCards

MgdGameElement >> newCardElement
  ^ MgdCardElement new
```

When we refresh the inspector we obtain a situation similar to the one of Figure 4-1. It shows that only a small part of the game is displayed. This is due to the fact that the game element did not adapt to its children.
4.3 Updating the container to its children

A layout is responsible for the layout of the children of a container but not of the container itself. For this, we should use constraints.

```smalltalk
MgdGameElement >> initialize
  super initialize.
  self layout: BlGridLayout horizontal.
  self constraintsDo: [:layoutCons | layoutCons horizontal fitContent. layoutCons vertical fitContent]
```

Now when we refresh our view we should get a situation close to the one presented in Figure 4-2, i.e., having just one row. Indeed we never mentioned to the layout that it should layout its children in to a grid, wrapping after four.

4.4 Getting all the children displayed

We modify the `memoryGame:` method to set the number of columns that the layout should handle.

```smalltalk
MgdGameElement >> memoryGame: aGameModel
  memoryGame := aGameModel.
  self layout columnCount: memoryGame gridSize.
  memoryGame availableCards do: [:aCard | self addChild: (self newCardElement card: aCard)]
```

Once the layout is set with the correct information we obtain a full board as shown in Figure 5-1.
To offer a better identification of the cards, we should add some space between each of them. We achieve this by using the message `cellSpacing` as shown below.

We take the opportunity to change the background color using the message `background:`. Note that a background is not necessarily a color but that color is polymorphic to a background therefore the expression `background: Color gray` is equivalent to `background: (BlBackground fill: Color gray)`.

```smalltalk
MgdGameElement >> initialize
    super initialize.
    self layout: BlGridLayout horizontal.
    self layout cellSpacing: 7.
    self background: (BlBackground fill: Color gray).
    self
        constraintsDo: [ :layoutCons |
            layoutCons horizontal fitContent.
            layoutCons vertical fitContent ]
```

Once this method is changed, you should get a situation similar to the one described by Figure 4-4.

We are now ready for adding interaction to the game.
Figure 4-4  Displaying a full board with space.
Now we will add interaction to the game. We want to flip the cards by clicking on them. Bloc supports such situations using two mechanisms: on one hand, event listeners handle events and on the other hand, the communication between the model and view is managed via the registration to announcements sent by the model.

### 5.1 An event listener

``` Smalltalk
BlElementEventListener subclass: #MgdCardEventListener
  instanceVariableNames: 'memoryGame'
  classVariableNames: ''
  package: 'Bloc-MemoryGame-Tutorial'

MgdCardEventListener >> memoryGame: aGameModel
  memoryGame := aGameModel

MgdCardEventListener >> clickEvent: anEvent
  self halt
```

We add an instance variable `memoryGame` holding a game model to the listener because we will need to access the model to react to events for example to update the game situation.

Let us redefine the `click:` method to raise a debugger. It will give us the occasion to introspect the system.
5.2 Adding event listeners

Now we should add the game event listener to each card because we want to know which card will be clicked and pass this information to the game model.

```smalltalk
MgdGameElement >> newCardEventListener
  ^ MgdCardEventListener new

MgdGameElement >> memoryGame: aGameModel
  memoryGame := aGameModel.
  self layout columnCount: memoryGame gridSize.

memoryGame availableCards
do: [:aCard |
  | cardElement |
  cardElement addEventHandler: (self newCardEventListener memoryGame: aGameModel).
  self addChild: cardElement ]
```

Now the preview is not enough and we should create a window and embedded the game element. Then when you click on an card you should get a debugger as shown in Figure 5-1.
5.3 Specialize clickEvent:

Now we can specialise the `clickEvent:` method as follows:

- we get the graphical element that receives the mouse click using the message `currentTarget`. The message `currentTarget` returns the element that receives an event.

- From this graphical card we access the card model and we pass this card model to the game model.

```plaintext
MgdCardEventListener >> clickEvent: anEvent
memoryGame chooseCard: anEvent currentTarget card
```

It means that the memory game model is changed but we do not see the visual effect of our actions. Indeed this is normal. We never made sure that visual elements are listening to model changes. This is what we will do in the following chapter.

5.4 Connecting the model to the UI

Now we show how the domain communicates with the user interface: the domain emits notifications using announcements but it does not refer to the UI elements. It is the visual elements that should register to the notifications and react accordingly.

Let us first define two simple methods in the class `CardElement` just producing a trace.

```plaintext
MgdCardElement >> onDisappear
  Transcript show: 'On disappear'; cr
MgdCardElement >> onFlipped
  Transcript show: 'On flipped'; cr
```

Now we can modify the setter so that when a card model is set to a card graphical element, we register to the notifications emitted by the model. In the following method, we make sure that on notifications we invoke the trace methods just defined.
Adding Interaction

Figure 5.2 Tracing registration to the domain notifications.

```smalltalk
MgdCardElement >> card: aMgCard
  card := aMgCard.
  card announcer when: MgdCardFlippedAnnouncement send: #onFlipped
to: self.
  card announcer when: MgdCardDisappearAnnouncement send:
    #onDisappear to: self

Now when you click on a card, you can see the trace in the Transcript but you do not see the changes. This is because we should notify the graphics engine that one element should be redrawn.

```smalltalk
MgdCardElement >> onFlipped
  Transcript show: 'On flipped'; cr.
  self invalidate

5.5 Handling disappear

There are two ways to implement the disappear of a card, either setting the opacity of the element to 0.

```smalltalk
MgdCardElement >> onDisappear
  Transcript show: 'On disappear'; cr.
  self opacity: 0.
  self invalidate.

Note that the element is still present and receive events.

Or changing the visibility as follows:

```smalltalk
MgdCardElement >> onDisappear
  Transcript show: 'On disappear'; cr.
  self visibility: BlVisibility hidden.
  self invalidate. "not needed in the latest Bloc"
```
5.6 Refreshing on missed pair

When the player selects two cards that are not a pair, we present the two cards as shown in Figure 5-4. Now the clicking on another card will flip back the previous cards.

Remember a card when flipped in either sense will raise a notification.

```smalltalk
MgdCardElement >> flipped: aBoolean
  flipped := aBoolean.
  self notifyFlipped
```

In the method `choseCard:` we see that all the previous cards are flip (toggled).

```smalltalk
... (self chosenCards size > self matchesCount) ifTrue: [
  self chosenCards allButLastDo: [ :each | each flip ].
  self chosenCards removeAll.
  self chosenCards add: aMgCard ]
...```

Figure 5-3  Selecting two cards that are not in pair.

Note that in the last case the element does not get events. It is used for layout.

5.7 Conclusion

At this stage you are done for the simple interaction. Future versions of this document will explain how to add animations.
